ENR202 Mechanics of Materials Lecture 4B Slides and Notes

Slide 2

Welcome to lecture summary 4b. In this lecture summary, we will continue looking at shear force diagrams and bending moment diagrams. In the last two lecture summaries, we learnt how to draw shear force diagrams and bending moment diagrams using the equilibrium method based on the principles of important points. In this presentation, we will learn a second method, the graphical method.

Requirement for students

- To be able to draw SFD and BMD quickly and correctly by graphical method

In this lecture summary, you will learn how to draw Shear Force Diagrams and Bending Moment Diagrams quickly and accurately using the graphical method.

University of
South Australia

ENR202 4b -- Slide No. 4

Graphical Method (1)

Construct shear force and bending moment diagrams based on the relations among distributed load, shear, and moment.

Figure 1

Figure 2

The graphic method is based on the relationship between shear force and external loading and the relationship between bending moment and shear force. We can draw the shear force diagram and bending moment diagram based on these two relationships. The graphical method is an easier method to use.

University of
South Australia

Graphical Method (2)

ENR202 4b -- Slide No. 5

Construct shear force and bending moment diagrams based on the relations among distributed load, shear, and moment.

Figure 1

Figure 2

Let's say that a beam is subjected to various types of lateral loads such as a uniform distributed load ' w ' and point load ' P ', as shown in Figure 1. We can analyse one small segment of the beam ' dx ' at a distance of ' x ' from the left support, as shown in Figure 1. In this small segment, we have two cutting cross sections.

We have already discussed that we have two internal force actions at a cutting cross section. They are the shear force and the bending moment. We can see positive shear force and positive bending moment at the cutting cross section. (You should be familiar with the sign conventions for shear force and bending moment at a cutting cross section).

On the left cutting cross section, we have a positive shear force ' V ' acting in an upward direction and rotating the beam segment in a clockwise direction, and a positive bending moment ' M ', acting in a clockwise direction. So the top part of the beam is in tension and the bottom part of the beam is in compression, as shown in Figure 2.

On the right cutting cross section, we have a positive shear force ' V plus dV ', which is acting in a downward direction and rotates the beam segment in a clockwise direction, and we have a positive bending moment ' M plus dM ', which is acting in an anti-clockwise direction. So the top part of the beam is in compression and the bottom part of the beam is in tension, as shown in Figure 2.

The shear force and bending moment at the right side cross section is different from the shear force and bending moment at the left side cutting cross section. The free body diagram of this beam segment also includes the external loads acting on the

ENR202 Mechanics of Materials Lecture 4B Slides and Notes

beam segment, so we have distributed loadings acting on the beam segment as shown in Figure2.

University of
South Australia

Graphical Method (3)

ENR202 4b -- Slide No. 6

$$\sum F_y = 0$$

$$V + w \cdot dx - (V + dV) = 0 \rightarrow (1)$$

$$dV/dx = w \rightarrow (2)$$

The slope of the shear diagram must everywhere be equal to the value of the applied loading.

As you know, if the structure is in equilibrium, it means that all structural parts are in equilibrium. Therefore, the beam segment 'dx' is also in equilibrium. In this figure, we can see a positive shear force and a positive bending moment at the left and right cutting cross sections, and the resultant uniform distributed load 'w times dx'. Now we can apply the equilibrium equation that is all forces in a vertical direction are equal to zero.

The shear force 'V(x)' is acting in an upward direction at the left cutting cross section. The shear force 'V plus dV' is acting in a downward direction at the right cutting cross section. The resultant uniform distributed load 'w times dx' is acting in an upward direction. So we get equation 1, that V plus 'w times dx' minus 'V plus dV' is equal to zero.

Now we can see the relationship between the shear force and external distributed load. It is 'w' equal to 'dV' divided by 'dx', which means the first derivative of the shear force is 'w'. Therefore, the slope of the shear force diagram must be equal everywhere to the value of the applied loading.

ENR202 4b -- Slide No. 7

Graphical Method (4)

We may express the shear V in terms of vertical forces w by integrating:

$$\int_{V_0}^V dV = \int_{x_0}^x w dx \quad \rightarrow (3)$$

$V - V_0 = (\text{total vertical force from } x_0 \text{ to } x) \quad \rightarrow (4)$

$V = V_0 + (\text{total vertical force from } x_0 \text{ to } x) \quad \rightarrow (5)$

in which V_0 is the shear force at x_0 and V is the shear force at x .

Vertical force will be positive if in up direction and be negative if in down direction.

If you rearrange equation 2 and integrate both side of the equation, you will get equation 3, as shown in the slide. The limits of the integration on the left side of the equation is the shear force at the left side cutting cross section, which is ' V_0 ', to the shear force at the right side cutting cross section, which is ' V '. The limits of the integration on the right side of equation is the distance of the left side cutting cross section from the left support, which is ' x_0 ', to the distance of the right side cutting cross section from the left support, which is ' x ', as shown in Equation 3.

Once you integrate the left side of the integration, you will find out the shear force ' V minus V_0 ', equals the right side of the integration is the total vertical force from distance ' x_0 ' to distance ' x ', as in Equation 4.

Note that the shear force at the left cutting cross section and at a distance of x_0 is V_0 , and the shear force at the right cutting cross section and at a distance of x is V .

In the graphical method, we start by calculating the shear force from the left side of the beam. Once we know the shear force at the left side of the beam, then we can calculate the right side of the beam. The shear force at the right side of the beam ' V ' is equal to the shear force at the left side of the beam ' V_0 ' plus the total vertical force from x_0 to x ', as in Equation 5. Note that the external load acting upwards has a positive shear force, so we use a positive sign, and the external load acting downwards has a negative shear force. (Make sure that you are familiar with sign conventions.)

University of
South Australia

ENR202 4b -- Slide No. 8

Graphical Method (5)

We may express the shear V in terms of vertical forces w by integrating:

$$\int_{V_0}^V dV = \int_{x_0}^x w dx \quad \rightarrow (3)$$
$$V - V_0 = (\text{total vertical force from } x_0 \text{ to } x) \quad \rightarrow (4)$$
$$V = V_0 + (\text{total vertical force from } x_0 \text{ to } x) \quad \rightarrow (5)$$

in which V_0 is the shear force at x_0 and V is the shear force at x .

Vertical force will be positive if in up direction
and be negative if in down direction.

We will start with the shear force at the left side cutting cross section, then calculate the shear force at the right side cross section. The shear force at the left side of the beam is ' V_0 ', which is equal to the shear force at the right side of the beam ' V ' minus the total vertical force from x_0 to x '. If the external load is acting upwards, the shear force is negative, and if the external load is acting downwards, the shear force is positive. Because the external load is acting upwards, we use a negative sign.

University of
South Australia

ENR202 4b -- Slide No. 9

Graphical Method (6)

$$\sum M_{left} = 0$$

$$M - w * dx * dx / 2 + (V + dV) dx - (M + dM) = 0 \rightarrow (6)$$

$$dM/dx = V \rightarrow (7)$$

The shear everywhere is equal to the slope of the moment curve.

We know that the beam segment 'dx' is in equilibrium. In this figure, we can see positive shear force and positive bending moment at the left and right cutting cross sections, and the resultant uniform distributed load 'w times dx'. Now, we can apply the equilibrium equation which says that all force moments at the left cutting cross section point are equal to zero.

The moment of shear force 'V(x)' at the left cutting cross section is zero because 'V(x)' is acting at the left cross section. The moment of the shear force 'V plus dV' at the left cutting cross section is 'V plus dV' times 'dx' in a clockwise direction. The moment of the resultant uniform distributed load 'w times dx' times 'dx divided by 2' is in an anti-clockwise direction. The moment 'M(x)' acting at the left cutting cross section is in a clockwise direction. The moment 'M plus dM' acting at the right cutting cross section is in an anti-clockwise direction as in Equation 6. Simplify Equation 6, and ignore the term 'square dx' and you will get Equation 7. Equation 7 outlines the relationship between the bending moment and the shear force, and means that the first derivative of moment is shear force. Therefore, the shear everywhere is equal to the slope of the moment curve.

University of
South Australia

ENR202 4b -- Slide No. 10

Graphical Method (7)

We may express the moment M in terms of the shear V by integrating:

$$\int_{M_0}^M dM = \int_{x_0}^x V dx \rightarrow (8)$$

$M = M_0 + (\text{area under shear diagram from } x_0 \text{ to } x) \rightarrow (9)$

in which M_0 is the bending moment at x_0 and M is the bending moment at x .

Now rearrange Equation 7 and integrate both side of the equation, to get Equation 8 as shown in the slide. The limits of the integration of the left side of the equation is the moment at the left side cutting cross section, which is ' M_0 '. The moment at the right side cutting cross section is ' M '. The limits of the integration of the right side of the equation is the distance of the left side cutting cross section from the left support, which is ' x_0 ' to the distance of the right side cutting cross section from the left support, which is ' x ', as shown in Equation 8.

Once you integrate the left side of the integration, you get moment ' M minus M_0 ', and the right side of the integration is the area under the shear force diagram from ' x_0 ' to ' x ', as in Equation 4.

Note that the moment at the left cutting cross section and at a distance of x_0 is M_0 . The moment at the right cutting cross section and at a distance x is M .

University of
South Australia

ENR202 4b -- Slide No. 11

Graphical Method (8)

We may express the moment M in terms of the shear V by integrating:

$$\int_{M_0}^M dM = \int_{x_0}^x V dx \rightarrow (8)$$

$M = M_0 + (\text{area under shear diagram from } x_0 \text{ to } x) \rightarrow (9)$

in which M_0 is the bending moment at x_0 and M is the bending moment at x .

In the graphical method, we calculate the moment from the left end to the right end of the beam.

The moment at the right side of the beam ' M ' is equal to the moment at the left side of the beam ' M_0 ' plus the area under the shear force diagram from x_0 to x ', as in Equation 9.

If the area under the shear force diagram is positive, use a positive sign to calculate the moment at the right side cutting cross section. If the area under the shear force diagram is negative, use a negative sign to calculate the moment at the right side cutting cross section.

University of
South Australia

ENR202 4b -- Slide No. 12

Graphical Method (9)

By combining the relations of loading, shear and moment, we have:

$$d^2M/dx^2=w \rightarrow (10)$$

if w is a known function of x , the moment M may be obtained by two integrations, provided that the limits of integration are properly evaluated each time. This method is usable only if w is a continuous function of x .

If you combine the relationship between shear force and external loading, and the relationship between bending moment and shear force, you get Equation 10. If external loading 'w' is a known function of x , then you can work out bending moment M by two integrations, provided that the limits of integration are properly evaluated each time. However, you can only use this method if the external load 'w' is a continuous function of x , which means a uniform distributed load, or triangle (linearly varied) distributed load.

In this slide, we know shear force and bending moment at A, and we need to calculate shear force and bending moment at B. We present two cases.

Case I: In a beam, we consider a beam segment between point A (on the left side of the beam segment cross section) and point B (on the right side of the beam segment cross section) and we show a positive shear force and positive bending moment at points A and B, as shown in the figure. Here, we know the shear force at A and we assume the resultant external load is acting in an upward direction. We need to calculate the shear force at point B, which is equal to the shear force at A plus an external load acting on the beam segment.

Case II: In a beam, we consider a beam segment between points A and B as shown in the figure. Here, we know the shear force at point A and we assume that the resultant external load is acting in a downward direction. We need to calculate the shear force at point B, which is equal to shear force at A minus the external load acting on the beam segment.

Case I: In a beam, we know the bending moment at A and we assume the area under the shear force diagram is positive. We need to calculate the bending moment at B, which is equal to the bending moment at A plus the area of the shear force diagram.

Case II: In a beam, we know the bending moment at A and we assume the area under the shear force diagram is negative. We need to calculate the bending moment at B, which is equal to the bending moment at A minus the area of the shear force diagram.

We will refer to these figures in next four slides. We have a point load in Case A, a concentrated moment in case B, a uniformly distributed load in case C, a linearly increasing load in case D, and a linearly decreasing load in case E. We have a shear force diagram and a bending moment diagram in each case, as shown in the figures.

Let's consider a beam segment with a left side cross section denoted as point 1 and a right side cross section denoted as point 2.

 **Useful Deductions for construction of shear force diagram**

ENR202 4b -- Slide No. 15

- Concentrated loads on the structure result in sudden jumps in the shear force diagram. The magnitude of these changes is equal to the magnitude of the forces. The direction of the changes is the same as the direction of the forces causing them.
- If there is no loading on the beam between any two concentrated loads, the shear force diagram has a constant value.

In case A, if a point load or a concentrated load is acting on a beam segment, there is a sudden jump in the Shear Force Diagram at that point load. If there is no load acting on the beam segment between any two point loads, the Shear Force Diagram has a constant value.

 **Useful Deductions for construction of shear force diagram**

ENR202 4b -- Slide No. 16

- The shear force diagram increases or decreases at a constant rate under a uniformly distributed load. The slope of the shear force diagram is equal to the magnitude of the uniformly distributed load.
- The shear force diagram changes according to a parabolic function under linearly ranging loads. The slope of the shear force diagram at any point on the beam is equal to the magnitude of the distributed load at the point in question.
- The shear force must be zero at a free end of the beam.

In case C, there is a uniformly distributed load acting on a beam segment. There is a linear increase or decrease in the Shear Force Diagram at the Uniformly Distributed Load.

In cases D and E, there is a linearly increasing or decreasing load acting on a beam segment. There is a parabolic function in the Shear Force Diagram under linearly ranging loads. The slope of the Shear Force Diagram at any point on the beam is equal to the magnitude of the distributed load at that point.

The shear force must be zero at the free end of the beam, because there is no shear force at the free end of the beam.

 ENR202 4b -- Slide No. 17

Useful Deductions for construction of bending moment diagram

- The bending moment diagram changes linearly between any two concentrated loads on a beam.
- The bending moment diagram is a parabolic curve for a uniformly distributed load.
- The bending moment diagram is a cubic function for a linearly varying distributed load.

In case A, if there is a point load or concentrated load acting on a beam segment, there is a linear variation in the Bending Moment Diagram.

In case C, if there is a uniformly distributed load acting on a beam segment, there is a parabolic variation in the Bending Moment Diagram.

In cases D and E, if there is a linearly varying distributed load acting on a beam segment, there is cubic variation in the Bending Moment Diagram.

**Useful Deductions for construction of bending moment diagram**

ENR202 4b -- Slide No. 18

- The bending moment is zero at roller pinned and roller supports of simply supported beams, as well as the free end of cantilever beams, unless a concentrated moment is applied at this location.
- When the loading includes an externally applied moment, the internal bending moment diagram will exhibit a sudden jump. The magnitude of this sudden change will equal the magnitude of the applied moment. Concentrate moment in clockwise direction is positive (cause increase in bending moment) and anti-clockwise moment is negative.

The bending moment is zero at the roller supports and hinged supports of a simply supported beam. There is no bending moment at the free end of a cantilever beam.

In case B, if there is a concentrated moment acting on the beam segment, there is a sudden jump in the Bending Moment Diagram. The jump is equal to the concentrated moment acting on the beam segment. If the concentrated moment is acting in an anti-clockwise direction, the jump will be downwards.

Remember these points, because they are valuable when drawing Shear Force Diagrams and Bending Moment Diagrams.

ENR202 4b -- Slide No. 19

University of South Australia

Procedure for Analysis

- Calculate Reactions
Draw the free body diagram of the beam and determine the support reactions. Resolve the forces acting on the beam into components that are perpendicular and parallel to the beam's axis.

This is the procedures for drawing Shear Force Diagrams and Bending Moment Diagrams in the graphical method. As you know, the first step is to calculate the reaction forces at the supports.

University of
South Australia

ENR202 4b -- Slide No. 20

Procedure for Analysis

- Important points
Separate beams into small segments based on important points: Supporting points, loading changing points (start and end of distributed loads, concentrate loading points and concentrate moment points)

Then separate the beam into several small beam segments. The separating points should be the important points, such as the supporting points and loading changing points (this could be the start or end points for a distributed load, or the concentrated loading point, or the concentrated moment point).

University of
South Australia

ENR202 4b -- Slide No. 21

Procedure for Analysis

- Draw shear force diagram (SFD)
From left end to right end, calculate shear forces at the important points. Remember, there are two values at a concentrate loading point (V_L and V_R)
Formula ; $V_R = V_L + P$ (external loadings q and P are positive with up direction; negative with down direction).
 V shall start with 0 and end with 0.
Connect V values at important points using straight lines (For a beam segment with $q=0$, or a constant q).

Now calculate the shear forces at important points from the left end to the right end. We know the shear force at the left end and we can calculate the shear force at right end. Consider the left and right side of an important point if there is a concentrated load acting at that important point. Use the formula which states that the shear force at the right side of the beam segment, which is V_R , is equal to the shear force at the left side of the beam segment, which is V_L , plus all the forces in the beam segment. The shear force starts with zero and ends with zero. Just connect the shear forces values at important points using straight lines to get the shear force diagram.

University of
South Australia

ENR202 4b -- Slide No. 22

Procedure for Analysis

- Draw bending moment diagram (BMD)

From left end to right end, calculate bending moment at the important points. Remember, there are two values at a concentrate moment point (M_L and M_R)

Formula ; $M_R = M_L + M_0$ (external loading M_0 is positive with clockwise direction; negative with anticlockwise direction).

M shall start with 0 and end with 0. Maximum M happens with $V=0$.

Connect M values at important points with straight line (for a beam segment with $q=0$), or parabolic line (for a beam segment with nonzero q).

The process for the bending moment diagram is similar to that for the shear force diagram. Working from the left end to the right end, start with zero and end with zero. Calculate the bending moment at the important points, using the formula which states that the bending moment at the right side of the beam segment, which is M_R , is equal to the bending moment at the left side of the beam segment, which is M_L , plus shear force diagram area between the two points.

The bending moment starts with zero and ends with zero. The maximum bending moment happens when the shear force is equal to zero (this is because the first derivative of bending moment is equal to the shear force. Where the derivative is zero, there is the maximum value.)

Finally, connect the bending moment values at the important points with straight lines for the segments without any distributed load, or parabolic lines for non-zero distributed loads.

University of
South Australia

ENR202 4b -- Slide No. 23

Example and Solution (1)

Step 1: Reaction forces
 $R_A = 20\text{kN}$ $R_C = 10\text{kN}$
Step 2: important points A, B, C

Let's look back at the example which we worked through in Lecture 4a, a simply supported beam is subjected to a concentrated load or point load of 30 kilo Newtons at Point B, which is at a distance of 2 meters from point A, as shown in the figure. The total length of the beam is 6 meters.

Suppose that you are required to draw a Shear Force Diagram and Bending Moment Diagram for this simply supported beam.

The first step is to calculate the reaction forces. We already calculated the reaction forces in Lecture 4a (in slide 6). (If you need to, go back and have a quick look at how we did those calculations.) The reaction force at point A is equal to 20 kilo Newtons, and the reaction force at Point C is equal to 10 kilo Newtons.

For the second step, we need to find the number and position of the important points. We have three important points. Two are support points, Point A and Point C. A further important point is the concentrated load at Point B. As we have discussed, if we have a concentrated load, you need to consider the left and rights sides of Point B to calculate the shear force.

University of
South Australia

ENR202 4b -- Slide No. 24

Example and Solution (2)

All external forces including reaction forces and loads are known with $R_A=20\text{kN}$ $R_C=10\text{kN}$

Rule: The change of shear force between two points is the external forces between the two points. Up is positive, down is negative.

From left to right, calculate shear force at both sides "left and right" of A, B, C

Step 3: Draw SFD
Start with 0 and end with 0

A left: $V_A^L=0$
 A right:
 $V_A^R=V_A^L+R_A=0+20=20\text{kN}$
 B left: $V_B^L=V_A^R=20\text{kN}$
 B right:
 $V_B^R=V_B^L-30=20-30=-10\text{kN}$
 C left: $V_C^L=V_B^R=-10\text{kN}$
 C right:
 $V_C^R=V_C^L+R_C=-10+10=0\text{kN}$

The shear force starts with zero and ends with zero, and you need to calculate shear force from left end to right end. If we have a concentrated load, you must consider the left and right sides of that point to calculate the shear force. Here, the reaction force R_A and R_C are also concentrated loads. So to calculate shear force, you need to consider the left and right side of point A because of the reaction force R_A , and the left and right side of point B because of the point load at B, and the left and right side of point C because of the reaction force R_C .

If the external forces or reaction forces between the two points act in an upward direction, they are positive, and if they are in a downward direction, they are negative.

The reaction force R_A is 20 Kilo Newtons, the concentrated load is 30 Kilo Newtons, and the reaction force at C, which is R_C , is 10 Kilo Newtons.

University of
South Australia

ENR202 4b -- Slide No. 25

Example and Solution (3)

All external forces including reaction forces and loads are known with $R_A=20\text{kN}$ $R_C=10\text{kN}$

Rule: The change of shear force between two points is the external forces between the two points. Up is positive, down is negative.

From left to right, calculate shear force at both sides "left and right" of A, B, C

Step 3: Draw SFD
Start with 0 and end with 0

A left: $V_A^L=0$
 A right:
 $V_A^R=V_A^L+R_A=0+20=20\text{kN}$
 B left: $V_B^L=V_A^R=20\text{kN}$
 B right:
 $V_B^R=V_B^L-30=20-30=-10\text{kN}$
 C left: $V_C^L=V_B^R=-10\text{kN}$
 C right:
 $V_C^R=V_C^L+R_C=-10+10=0\text{kN}$

We have three important points: A, B and C. To draw the shear force diagram, we will start with the left end. Consider just to the left of Point A. At Aleft we have zero shear force because the shear force starts with zero. Then we come to Aright. Between Aleft and Aright, we have a concentrated load. That is, R_A equals 20 Kilo Newtons in an upward direction. We know that upward is positive. Finally we get Aright equals 20 Kilo Newtons.

When we come to Bleft, we don't have any vertical force between Aright to Bleft. So Bleft equals 20 kilo Newtons. Move on to Bright. We should have a jump of 30 Kilo Newtons because we have a concentrated load of 30 kilo Newtons. Bright equals 20 kilo Newtons minus 30 kilo Newtons, which is negative 10 Kilo Newtons. We come to Cleft. We don't have any vertical force from Bright to Cleft. So Cleft equals minus 10 kilo Newtons. Move on to Cright. We should have a jump of 10 Kilo Newtons, because we have a reaction force R_C which is 10 kilo Newtons acting in an upward direction. Cright equals minus 10 kilo Newtons plus 10 kilo Newtons, which is zero. We can see that the shear force ends with zero. Therefore, we know that the values are correct.

University of
South Australia

ENR202 4b -- Slide No. 26

Example and Solution (4)

From left to right, connect shear forces at important points using straight lines from A left, A right, B left, B right, C left to C right and we can have the shear force diagram (SFD)

Step 3: Draw SFD
Start with 0 and end with 0
 A left: $V_A^L = 0$
 A right:
 $V_A^R = V_A^L + R_A = 0 + 20 = 20\text{kN}$
 B left: $V_B^L = V_A^R = 20\text{kN}$
 B right:
 $V_B^R = V_B^L - 30 = 20 - 30 = -10\text{kN}$
 C left: $V_C^L = V_B^R = -10\text{kN}$
 C right:
 $V_C^R = V_C^L + R_C = -10 + 10 = 0\text{kN}$

Connect all the values at the important points, and we get shear force diagram as shown in the figure here. Try to draw the shear force diagram on your own and check your work against this figure.

University of
South Australia

ENR202 4b -- Slide No. 27

Example and Solution (5)

SFD is known now.

Rule: The change of M between two points is the area of SFD between the two points.

From left end to right end, calculate bending moment at A, B, C points based on the rule above.

Step 4: Draw BMD

Start with 0 and end with 0

A: $M_A = 0$

B: $M_B = M_A + \text{Area in SFD between A and B}$
 $M_B = M_A + 20\text{kN} \cdot 2\text{m}$
 $= 0 + 40 = 40\text{kN}\cdot\text{m}$

C: $M_C = M_B + \text{Area in SFD between B and C}$
 $M_C = M_B + (-10\text{kN}) \cdot 4\text{m}$
 $= 40 - 40 = 0\text{kN}\cdot\text{m}$

In the previous slides, we worked out the shear force diagram for this example. We are now going to draw the bending moment diagram based on the shear force diagram.

Again, we start with the left end and then go back to the right end. We have three important points, A, B and C. We already know that there is no bending moment at the roller support nor at the hinged supports. Therefore, the bending moment at Points A and C is equal to zero.

We also know that bending moment starts with zero and ends with zero. Therefore, the bending moment at A is equal to zero. The bending moment at B is equal to the bending moment A plus the area under the shear force diagram between Points A and B because the Shear Force Diagram is positive. The shear force area between A and B is 20 kilo Newtons times 2 meters, which is equal to 40 kilo Newton meters. This shear force diagram is positive between A and B. Finally, we calculate the bending moment at B which is 40 kilo Newton meters.

Then we move on to Point C. The bending moment at C is equal to the bending moment at B minus the area under the shear force diagram between Points B and C because the Shear Force Diagram is negative. The shear force area between B and C is 10 kilo Newtons times 4 meters, which is 40 kilo Newton meters. This shear force diagram is negative between B and C. We calculate the bending moment at C using 40 kilo Newton meters at Point B minus 40 kilo Newton meters which is the area of the Shear Force Diagram. Therefore, the bending moment at C equal to zero. Bending moment should end with zero, and the bending moment at point C (which is the last point) is also zero. That means our calculations are correct.

South Australia

ENR202 4b -- Slide No. 28

Example and Solution (6)

Connect bending moments **from left end to right end** at important points using straight lines (why not parabola here ???) from A, B to C and we can have the bending moment force diagram (BMD)

Step 4: Draw BMD
Start with 0 and end with 0
 A: $M_A = 0$

B : $M_B = M_A + \text{Area in SFD between A and B}$
 $M_B = M_A + 20\text{kN} \cdot 2\text{m}$
 $= 0 + 40 = 40\text{kN-m}$

C : $M_C = M_B + \text{Area in SFD between B and C}$
 $M_C = M_B + (-10\text{kN}) \cdot 4\text{m}$
 $= 40 - 40 = 0\text{kN-m}$

Connect the bending moment values at the important points from the left end to the right end using a straight line from A to C, and we get the bending moment diagram shown in the figure. Try drawing the bending moment diagram yourself and checking it against this figure.

Now pause this presentation and try to work through this exercise. You must draw a shear force diagram and a bending moment diagram for an overhang beam subjected to a uniform distributed load of 5 kilo Newtons per meter on the overhang portion that is between Point C and D, and the point load acting at point B as shown in the figure. Draw the Shear Force Diagram and Bending Moment Diagram using the graphical method. The solution is on the next slide.

First, calculate the reaction forces at the supports at points A and C. Next, work out the number and position of the important points. There are four important points.

The shear force starts with zero and ends with zero. You need to calculate the shear force from the left end to the right end. If we have a concentrated load, you must consider the left and right side of that point to calculate the shear force. Here, the reaction forces R_A and R_C are also concentrated loads. So to calculate shear force, you need to consider the left and right side of point A because of the reaction force R_A , the left and right side of point B because of the point load at B, and the left and right side of point C because of the reaction force R_C .

Once you know shear force values at important points, connect them from the left end to the right end using a straight line from A to D. You will get the shear force diagram as shown in the figure.

Now, calculate the bending moment values at important points, and connect all the bending moment values to draw the Bending Moment Diagram.

ENR202 3b -- Slide No. 31

Formula for Concentrated moment

$$A_L + 80 - A_R = 0 \Rightarrow A_R = A_L + 80$$

$$A_L - 80 - A_R = 0$$

$$A_R = A_L - 80$$

Now let's look at the case of a concentrated moment acting on a beam segment.

Suppose that we have a concentrated moment of 80 kilo Newton meters in a clockwise direction acting on the beam segment as shown in the top figure. The left side cutting cross section has a positive bending moment A_L that is in a clockwise direction. The right side cutting cross section has a positive bending moment A_R that is in an anti-clockwise direction. We know the value of the bending moment in the left side cross section. We need to calculate the value of the bending moment in the right side cross section. We use the equation which states that A_R is equal to A_L plus 80 kilo Newton meters. If there is a clockwise concentrated moment acting on the beam segment, we use a positive sign to calculate the right side moment.

There is a concentrated moment of 80 kilo Newton meters in an anti-clockwise direction acting on the beam segment as shown in the bottom figure. The left side cutting cross section has a positive bending moment A_L that is in a clockwise direction. The right side cutting cross section has a positive bending moment A_R that is in an anti-clockwise direction. We know the value of the bending moment in the left side cross section. We need to calculate the value of the bending moment in the right side cross section. We use the equation which states that A_R is equal to A_L minus 80 kilo Newton meters. If there is an anti-clockwise concentrated moment acting on the beam segment, we use a negative sign to calculate the right side moment.

Now pause this presentation and try to work through this exercise. An overhang beam is subjected to a uniform distributed load of 1 kilo Newton per meter between Point A and B as shown in the figure, and a concentrated moment of 12 kilo Newton meters acting in the middle between B and C. Draw the Shear Force Diagram and the Bending Moment Diagram.

Hint: The first step is to calculate the reaction forces at the supports at Points B and C. Next, work out the number and position of the important points. Then calculate the shear force and bending moment values at the important points. Then connect all shear force values to draw the Shear Force Diagram and connect all bending moment values to draw the Bending Moment Diagram.

The solution is given in the next four slides.

ENR202 4b -- Slide No. 33

Exercise 2: solution (1)

Step 1: Reaction forces

$$\Sigma M_C = 0 \quad R_B * 16m - 12kN \cdot m - 4kN * 18m = 0 \quad R_B = 5.25kN$$

$$\Sigma M_A = 0 \quad -4kN * 2m - 12kN \cdot m - R_C * 16m = 0 \quad R_C = -1.25kN$$

Check $\Sigma F_y = 0$ (???) $R_B + R_C - 4kN = 0$ (!) OK!

We know the first step is to calculate the reaction forces at the supports. There are two reaction forces at B and C, which are R_B and R_C , so we need two equilibrium equations.

The first equilibrium equation is that the sum of all force moments about C is equal to zero. That means that you consider Point C as a lever, as we covered in lecture 3a. We have four force moments about C. The first is the moment of reaction force R_B about C, which is R_B times 16 meters in a clockwise direction. The second is the moment of the uniform distributed load of 1 kilo Newton per meter about C. That means the resultant UDL is 1 kilo Newton per meter times 4 meters, which is 4 kilo Newtons times 8 meters plus 8 meters plus 2 meters, which equals 18 meters in an anti-clockwise direction. The third is a concentrated moment of 12 kilo Newtons meters in an anti-clockwise direction. Finally, we can calculate reaction force R_B which is 5.25 kilo Newtons. The next equilibrium equation is that all forces in a vertical direction are equal to zero. The downward force is the resultant UDL of 4 kilo Newtons. We already know the reaction force R_B is 5.25 kilo newtons acting in an upward direction. Finally, we see that the reaction force at C is equal to minus 1.25 kilo newtons. That means the R_C is down.

For the next step, we again need to find the number and positions of the important points. We have four important points. Point A is the beginning of the UDL, point B is the end of the UDL, and also a supporting point. Point D is a concentrated moment, and point C is another supporting point.

You have already calculated reaction forces. You can draw a shear force diagram based on vertical forces. These vertical forces include external loads and reaction forces. Based on the shear force diagram, you can draw a bending moment diagram from the left end to the right end. It starts with zero and ends with zero.

We start with Point A. We have zero shear force at point A. Then we come to Point B. The total UDL is 4 Kilo Newton. We need to consider the left side of point B and the right side of point B, because of reaction force R_B .

Consider just to the left of Point B. V_B^L equals minus 4 kilo Newtons. Then we come to Bright. Between V_B^L and Bright, we have a concentrated load of P_B , which is equal to 5.25 Kilo Newtons in an upward direction. We know that upward is positive. We work out that Bright equals 1.25 Kilo Newtons.

When we come to Cleft, we don't have any vertical force between Bright to Cleft. So Cleft equals 1.25 kilo Newtons. Move on to Cright. We should have a jump of 1.25 Kilo Newtons. We have a reaction force of 1.25 kilo Newtons acting in a downward direction. Cright equals 1.25 kilo Newtons minus 1.25 kilo Newtons, which is equal to zero. The shear force ends with zero, so we know that the values are correct.

ENR202 Mechanics of Materials Lecture 4B Slides and Notes

Connect the shear force values at all the important points from left end to right end, you will have a shear force diagram.

To work out the bending moment diagram, start from Point A and end with Point C. Start with a zero bending moment and end with a zero bending moment. Start from the left side of the beam and end with the right side of the beam.

We have zero bending moment at Point A. Then we come to Point B. The total area of the shear force diagram between A and B is negative 8 Kilo Newton meters, which means that the area of the triangle is negative 8 Kilo Newton meters. Therefore the bending moment at B is negative 8 Kilo Newton meters. Then we come to Point D; we have concentrated moment, so we have to find the bending moments at Dleft and Dright. The area of the shear force diagram between B and D is 1.25 kilo Newtons times 8 meters, which is 10 kilo Newtons. This is a positive Shear Force Diagram, so the bending moment at Dleft equals negative 8 Kilo Newton meters plus 10 Kilo Newton meters, which equals 2 Kilo Newton meters. From Dleft to Dright we have a concentrated moment of 12 Kilo Newton meters jump, and this is a negative concentrated moment because it is an anti-clockwise moment. Therefore Dright equals 2 Kilo Newton meters minus 12 Kilo Newton meters, which is negative 10 Kilo Newton meters. From Dright to Point C, we have a positive shear force diagram, so the bending moment at C equals negative 10 Kilo Newton meters plus 10 Kilo Newton meters, which is zero.

ENR202 Mechanics of Materials Lecture 4B Slides and Notes

Connect the bending moment values at the important points from the left end to the right end using a straight line from B to C and between A and B. We have a Uniformly Distributed Load, so the bending moment diagram between A and B is parabolic. The top part AB will be negative and the bottom part AB will be positive, because the bending moment at B is negative and because the AB part is a cantilever beam. Try to draw the bending moment diagram on your own and check your work against this figure.

Pause the presentation and work through this example. A simply supported beam is subjected to a concentrated moment of 18 kilo Newton meters acting at B at a distance of 3 meters from the left support A, as shown in the figure. One point load is 8 kilo Newtons acting at Point C, at a distance of 6 meters from the left support, and another point load is 8 kilo Newtons acting at Point D at a distance of 8 meters from the left support, as shown in the figure. The total length of the beam is 10 meters. Draw the Shear Force Diagram and the Bending Moment Diagram. The solution is on the next six slides.

ENR202 4b -- Slide No. 38

Exercise 3: solution (1)

Step 1: Reaction forces

$$\sum M_E = 0 \quad R_A \cdot 10 + 18 - 8 \cdot 4 - 8 \cdot 2 = 0 \quad R_A = 3 \text{ kN}$$

$$\sum M_A = 0 \quad 18 + 8 \cdot 6 + 8 \cdot 8 - R_E \cdot 10 = 0 \quad R_E = 13 \text{ kN}$$

Check $\sum F_y = 0$ (???) $R_A + R_E - 16 \text{ kN} = 0$ (!) OK!

38

Firstly, calculate the reaction forces at the supports at points A and E.
 Next, work out the number and position of the important points.
 Next, calculate the shear force and bending moment values at the important points.
 Finally, connect all shear force values to draw the Shear Force Diagram and connect all bending moment values to draw the Bending Moment Diagram.

If you are still unsure of how to do this, the solution is given in more detail in the following slides.

ENR202 4b -- Slide No. 39

Exercise 3: solution (2)

Step 1: Reaction forces

$$\sum M_E = 0 \quad R_A \cdot 10 + 18 - 8 \cdot 4 - 8 \cdot 2 = 0 \quad R_A = 3 \text{ kN}$$

$$\sum M_A = 0 \quad 18 + 8 \cdot 6 + 8 \cdot 8 - R_E \cdot 10 = 0 \quad R_E = 13 \text{ kN}$$

Check $\sum F_y = 0$ (???) $R_A + R_E - 16 \text{ kN} = 0$ (!) OK!

39

We know the first step is the calculation of the reaction forces at the supports. Calculate the reaction forces at A and E. We have two reaction forces, R_A and R_E . We need two equilibrium equations. The first equilibrium equation is that the sum of all force moments about E is equal to zero. That means that you consider point E as a lever, as we explained in lecture 3a. We have four force moments about C. The first is the moment of reaction force R_A about C, which is R_A times 10 meters in a clockwise direction. The second is a concentrated moment of 18 kilo Newton meters in a clockwise direction. The third is the moment of concentrated load of 8 kilo Newtons at C about point E, which is 8 kilo Newtons times 4 meters. The fourth is the moment of another concentrated load of 8 kilo Newtons at D about point E, which is 8 kilo Newtons times 2 meters. Finally we calculate the reaction force R_A which is 3 kilo Newtons.

The next equilibrium equation is that all forces in a vertical direction are equal to zero. The downward force is 8 kilo Newtons plus 8 kilo Newtons, which is equal to 16 kilo Newtons. We already know that the reaction force R_A is 3 kilo newtons acting in an upward direction. Finally, the reaction force at E is equal to minus 13 kilo newtons acting in an upward direction.

Based on the reaction forces and vertical forces, we can draw the shear force diagram. We have five important points. Point A is a support point, point B is a concentrated moment point, point C is a point load, point D is another point load, and point E is a support point.

First we start with zero shear force and start from left end. So, Aleft is zero. When we come to Aright we have a reaction force R_A , so Aright is 3kN, so we have a jump in the Shear Force Diagram of 3 Kilo Newtons. From A to C, we don't have any vertical force, so we have a concentrated shear force. So, Cleft is equal to Aright, which is 3 Kilo Newtons. At Point C, we have a concentrated downward vertical force, so Cright equals 3 kilo Newtons minus 8 kilo Newtons, which is negative 5 kilo Newtons. From C to D, we don't have any distributed force, so Dleft is the same as Cright, which is negative 5 kilo Newtons. We have a concentrated downward force of 8 Kilo Newtons, and Dright equals negative 5 minus 8, which is negative 13 Kilo Newtons, so we have a jump in the shear force diagram at D of 8 Kilo Newtons. From Point Dright to Point Eleft, we don't have any vertical force. So Eleft is the same as Dright, which is 13 kilo Newtons. From Eleft to E right, we have a reaction force R_E which is 13 Kilo Newtons acting in an upward direction. Therefore Eright equals negative 13 kilo Newtons plus 13 kilo Newtons, which equals zero.

University of
South Australia

ENR202 4b -- Slide No. 41

Exercise 3: solution (4)

Draw SFD based on the important points

A left: $V_A^L = 0$

A right: $V_A^R = V_A^L + R_A = 0 + 3 = 3\text{kN}$

B : $V_B = V_A^R = 3\text{kN}$

C left: $V_C^L = V_B^R = 3\text{kN}$

C right: $V_C^R = V_C^L - 8 = 3 - 8 = -5\text{kN}$

D left: $V_D^L = V_C^R = -5\text{kN}$

D right: $V_D^R = V_D^L - 8 = -5 - 8 = -13\text{kN}$

E left: $V_E^L = V_D^R = -13\text{kN}$

E right: $V_E^R = V_E^L + R_E = -13 + 13 = 0\text{kN}$

Start with 0 and end with 0

Connect all the shear force values at the important points from the left end to the right end to get the shear force diagram, which you will see in the next slide.

Compare your work to this Shear Force Diagram. If it is the same, well done.

Based on the shear force diagram, we can get the bending moment diagram. Start from the left side and end with the right side. The bending moment at Point A is zero, and the area of the shear force diagram between A and B is 9 Kilo Newton meters. We have a concentrated moment at B of 18 Kilo Newton meters acting in a clockwise direction, so the bending moment at B_{left} is 9 Kilo Newton meters, and the bending moment at B_{right} is 9 Kilo Newton meters plus 18 Kilo Newton meters, which is equal to 27 Kilo Newton meters. From B_{right} to Point C, we can say that the total area of the shear force diagram between Points B and C is 9 Kilo Newton meters, so the bending moment at C equals 27 Kilo Newton meters plus 9 Kilo Newton meters, which is 36 Kilo Newton meters. From Point C to Point D, we have a negative area shear force diagram of 10 Kilo Newton meters, so the bending moment at D equals 36 Kilo Newton meters minus 10 Kilo Newton meters, which is 26 Kilo Newton meters. We have another negative area of shear force diagram between D and E of 26 Kilo Newton meters, so the bending moment at Point D is 26 Kilo Newton meters minus 26 Kilo Newton meters, which equals zero.

Connect all the bending moment values at important points to get the bending moment diagram.

Pause the presentation and work out your solution to this exercise. A simply supported beam is subjected to a concentrated load 15 kilo Newtons acting at the middle of the beam, a uniformly distributed load of 5 kilo Newtons per meter at the right half length of the beam, and a concentrated moment acting of 80 kilo Newtons meters acting at A, as shown in the figure. Draw the Shear Force Diagram and the Bending Moment Diagram.

The solution is in the next three slides.

Let's have look at solution for this example. This example is for a simply supported beam. The concentrated moment acting on left support is 80 kilo Newton meters, and the concentrated load acting in the mid span of the beam is 15 Kilo Newtons, with a distributed load of 5 Kilo Newtons per meter acting on the right half span of the beam. You are required to calculate the shear force diagram and the bending moment diagram.

We have three important points. Point A is a support, point B is a concentrated load and also beginning of the Uniformly Distributed Load. Point C is the end of the Uniformly Distributed Load and is also another support. The first thing you have to calculate is the reaction forces. Consider that all force moments at B equal zero; how many moments are there? There is one moment from RA, one concentrated moment, one moment from the Uniformly Distributed Load, and one moment from the concentrated load. All four moments together equal zero. In this equation, we have only one unknown, which is RA. So we can work out the RA is 5.75 Kilo Newtons. You can also calculate RC, which is our only unknown. All forces in the y-direction are zero. So, we can work out that RC is 34.25 Kilo Newtons.

Now let's look at how to draw the shear force diagram. The reaction force R_A is 5.75 Kilo Newtons, we have a concentrated moment of 80 Kilo Newton meters, a concentrated load of 15 Kilo Newtons, and a Uniformly Distributed Load of 5 Kilo Newtons per meter. R_C is 34.25 Kilo Newtons, and we have three important points, A, B and C. To draw the shear force diagram, we will start with the left end. Consider just to the left of Point A. At Aleft we have zero shear force and zero bending moment. Then we come to Aright. Between Aleft and Aright, we have a concentrated load R_A , which is equal to 5.75 Kilo Newtons in an upward direction, so Aright equals 5.75 Kilo Newtons.

When we come to Bleft, we don't have any vertical force between Aright and Bleft. So Bleft equals 5.75 Kilo Newtons. Move on to Bright. We should have a jump of 15 Kilo Newtons of concentrated load. Bright equals 5.75 kilo Newtons minus 15 kilo Newtons, which is negative 9.25 Kilo Newtons. We come to Cleft. The total UDL is 25 Kilo Newtons acting down. Cleft equals negative 9.25 kilo Newtons minus 25 kilo Newtons, which is negative 34.25 Kilo Newtons. From Cleft to Cright, we have a concentrated load R_C . Cright is equal to negative 34.25 kilo Newtons plus 34.25 kilo newtons, which is zero. Connect all the values at the important points from the left end to the right end, and we will get the shear force diagram.

Now let us look at the bending moment diagram. There is a concentrated moment 80kNm acting at A. We have other vertical forces and reaction forces. Again, we start with the left end and then back to the right end. We have 3 important points, A, B and C.

We start with A left. We have zero bending moment at A left. But we have a concentrated moment of 80 Kilo Newton meters acting at A, so we have a bending moment jump of 80 Kilo Newton meters in a clockwise direction. This is a positive bending moment as per the graphical method. At right equals 80 Kilo Newton meters.

The shear force area between A and B is 5.75 kilo Newtons times 5 meters. It is a positive Shear Force Diagram. The moment at B equals 80 Kilo Newton meters plus 5.75 kilo Newtons times 5 meters, which is 108.75 Kilo Newton meters. From Point B to Point C, we have to include the shear force area between B and C, which is negative, and is equal to 108.75 Kilo Newton meters.

The moment at C equals 108.75 Kilo Newton meters minus 108.75 Kilo Newton meters, which is zero. Finally, the bending moment at C is back to zero. Connect all the moment values at the important points. Connect with a straight line between A and B. From B to C we have a Uniformly Distributed Load, so connect with a parabolic line between B and C. All these values are positive. Finally we get bending moment diagram as shown in the figure.

ENR202 Mechanics of Materials Lecture 4B Slides and Notes

Slide 48

Thank you for your attention. In the next lecture summary, we start centroids, and moments of inertia, and bending stresses in beams.
